Fostering a Sustainable Community in Batteries

As with nearly all facets of daily life, the COVID-19 pandemic has upended the traditional routines for science outreach and collaboration for battery researchers of all stripes. In-person conferences, meetings, lab visitations, and sabbaticals have largely been cancelled or postponed, disrupting the typical avenues for communication between scientists, engineers, and researchers. Increasingly, researchers have developed creative ways to leverage electronic communication formats, harnessing growing online social media communities to create ad-hoc replacements for the essential functions served by these conventional in-person events. Concurrently, there has been a growing recognition of the fundamental tension between travel-intensive scientific networking and the stated goals of many research fields focused on *mitigating* anthropogenic climate change and environmental degradation. Recent analysis of a European economics conference estimated roughly 0.5 tonnes of CO_2 emissions per participant, while the University of California Santa Barbara recently estimated that conference travel accounts for roughly 30% of its carbon footprint.[1,2]

Within this context, an online battery modeling community has taken shape. Centered around weekly webinars and a free-flowing Slack workspace, the community fulfills a critical need for connection between battery researchers with diverse backgrounds and interests from all over the world.[3] The community provides new avenues for information exchange, networking, and collaboration, which we hope will persist and provide a template for global, decentralized, democratic, and emissions-friendly community-building in a post-COVID science landscape. In this article, we describe the formation of this community, clearly state its mission, discuss initial activities, and identify challenges and opportunities, moving forward.

Origins of the community: Following a successful inaugural event in 2019, the 2020

Oxford Battery Modeling Symposium (OBMS)[4] was held on March 16 and 17, right at the start of COVID-related shutdowns in Europe and North America. About a week before the meeting on March 10, the organizing committee decided to go virtual. The virtual symposium used conferencing software (Zoom) in webinar mode for all presentations and Q&A. Alongside, a messaging workspace (in Slack) was created for general discussion, which also provided an avenue for in-depth discussions amongst participants during the talks. Posters were uploaded to a messaging channel, and a subset of poster presenters were invited to present their work in the main presentation webinar. Most of the speakers also posted their slides in the messaging app. At the end of the symposium there was wide consensus that we had phenomenal momentum and the Slack community was gold. The text-driven messaging platform created a richer, more diverse dialogue with a flatter hierarchy than is typically supported at in-person conferences. Without the pressure of trying to fit discussions into crowded conference schedules, participants were able to pose and answer thought-provoking questions, respond with links to relevant citations, and carry the conversation forward over the course of days. However it was really the *combination* of webinar and messaging app that stood out as being more than the sum of its parts. Without the messaging app, the presentations would have been far less engaging, but without the presentations at specific dates/times, it would have been difficult to assemble everyone onto the messaging app. Having sufficient critical mass of engagement was pivotal in kick-starting the community.

Following this, we started the weekly Battery Modeling Webinar Series (BMWS). Online BMWS sessions have an open format, with frequent pauses for questions (on average one pause every 20 minutes), turning a presentation into a moderated organic discussion. At the time of writing this article, the webinar series had finished the first 11 webinars, with the next dozen already lined up. As described below, the webinar series covers a wide range of topics and has attracted a large, diverse, and highly engaged audience, leading to high impact for the early career researchers who have presented, so far.

The role of social media: The groundwork for a successful community was laid in part

by the burgeoning battery community on Twitter, who typically share and discuss content under the `#battchat` and `#batterytwitter` hashtags. Even before the pandemic, there has been a growing recognition that social media and other electronic communication tools such as Twitter and Slack can supplement conference interactions in ways that are more flexible, more democratic, and less transient.[5–8] Social media provides an additional avenue for early career researchers to network and establish identities that are unique from their advisors and mentors. This is especially important during the pandemic, which has sharply reduced the in-person networking opportunities that are critical for early career researchers.[6,9] Moreover, Twitter bots such as `@electrochemicat` and `@BatteryPapers`, which automatically tweet relevant battery and energy storage papers, are a useful way to keep up with the rapidly growing literature. The battery community on Twitter has established norms centered on open-ended and collaborative dialogue, which helped create the necessary preconditions for a coherent and vibrant online community. The battery Twitter community also actively raised public awareness of and advertised OBMS and BMWS via tweets with the `#OBMS20` and `#BMWS` hashtags, respectively, which were subsequently retweeted widely; a collage of OBMS and BMWS tweets is shown in Fig. 1. As a result, the BMWS community is diverse and hails from countries all over the world, as illustrated in Fig. 2.

Vision and mission for the community: We see this as a persistent and inclusive community focused on battery modeling (broadly interpreted), with a formal weekly seminar series, an accompanying newsletter with around ∼700 subscribers, and an informal communication platform on Slack. We think that this approach can provide great opportunities for industry engagement and input, as highlighted by community messages shown in Fig. 3.

The community and the seminar series have the following mission statements:

Community: Build an interdisciplinary global community of battery experts and enthusiasts to enable the free exchange of ideas, foster collaborations, and learn from one another.

Seminars: Create a platform for early career researchers (graduate students, postdoctoral scholars, junior faculty, early-career industry researchers and professionals) to discuss their

Figure 1: Social media has been pivotal in connecting the community and advertising and extending OBMS and BMWS virtual events.

Figure 2: Locations reported by the 650 unique BMWS participants via Zoom through June 2020.

work with a interdisciplinary community of battery modeling experts, spanning from science to engineering and economics.

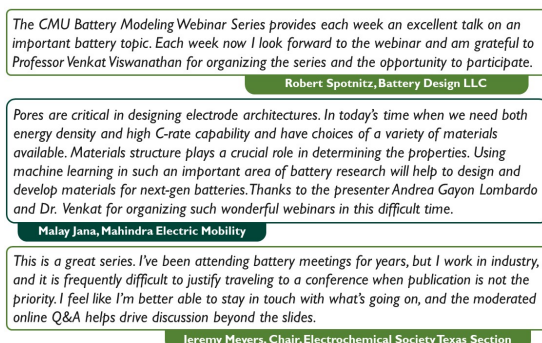

Figure 3: Community messages on the Webinar Series from industry researchers.

Wide range of battery modeling topics: The wide range of topics covered has helped broaden the knowledge-base of and form connections amongst the BMWS community, as indicated by community messages in Fig. 4. Here, we summarize the main insights from the talks so far (April-June 2020); an expanded version is given in the Supporting Information. The talks represent the wide range of focus and disciplines that fit under the banner of "battery modeling", as given in Table 1.

Figure 4: Community messages on the wide range of topics covered.

Microstructure modeling: The first seminar was by Ankit Verma on the understanding the influence of microstructure on the thermal and degradation (Li plating) behavior of Li-ion batteries.[10,11] Ankit showed that there is significant difference between heat generation using the commonly-employed Bruggeman approximation, as opposed to those obtained using the microstructures directly. Ankit also demonstrated how detailed microstructure analysis becomes important for fast charging applications. Andrea Gayon Lombardo presented on

generative adversarial networks to digitally generate realistic electrode microstructures.[12] Such deep learning methods can generate a range of electrode microstructures with less cost and effort than physical fabrication methods. These microstructures can then be used as input into battery simulations to guide development of new, high-performance electrodes.

Data-driven methods and modeling: Data-driven methods can accurately and efficiently predict charge-discharge performance and battery lifetime. Peter Attia demonstrated a machine learning (ML) approach to optimize a parameter space which dictates the current and voltage profiles during fast charging.[13] The approach utilizes Bayesian optimization[14] to identify fast charge protocols by sampling the design space efficiently. These methods have seen increasing use in searching design spaces of electrochemical systems.[15,16] Yunwei Zhang presented an approach to use Gaussian process regression on over 20,000 electrochemical impedance spectra (EIS) from cells with varying degrees of capacity degradation.[17] Gaussian processes have become popular recently for modelling battery health.[18,19] Last, Jiapeng Liu delivered a talk on metrics to assess EIS data quality. In their work, they have developed a Bayesian Hilbert transform to interpret impedance data.[20] Jiapeng also discussed metrics to score compliance of EIS data to Kramers-Kronig relation, and supplementing conventional metrics based on residuals and estimated means with information-theoretic concepts.[20]

Battery cost and resource modeling: Understanding current and future battery cost is crucial for a range of stakeholders. James Frith, Sam Korus and Vivas Kumar delivered thought-provoking talks on bottom-up and top-down approaches to cost modelling and supply chain considerations. As discussed further in the Supporting Information, Sam discussed Wright's Law,[21–23] which shows that historically, lithium-ion battery cost (USD/kWh) decreases by about 18 percent for every doubling in cumulative installed capacity. Using similar methods, James forecasts lithium-ion battery pack cost to reach 61 USD/kWh by 2030, compared to current costs of 150 USD/kWh.[24] James introduced the BNEF bottom-up, component-based cost model "BattMan", which highlights the importance of managing battery material costs, most notably the cathode.[25] Approaches to lowering battery cost

were discussed, including managing material costs, increasing battery energy density, yield, and utilization of manufacturing facilities. Finally, Vivas provided a deep dive into battery supply chain,[26] and pointed out the absence of commoditization in batteries, which enables differentiation of cathode chemistries for different applications and customers.[27]

Physics-based modeling: Xuning Feng discussed battery safety and electrochemical-thermal Li-ion battery models.[28] The talk discussed (i) rapid capacity degradation at high temperature, (ii) internal short circuits due to separator failure, and (iii) thermal runaway caused by heat release at extreme temperatures. Jorn Reniers reviewed an exhaustive list of existing models on capacity fade and battery degradation and compared them, demonstrating the extent to which the predictions from these models vary relative one another and to experimental data.[29] These comparisons were carried out with an open-source codebase developed along with the related publication.[30] Guanchen Li presented work on electro–chemo–mechanical coupling to explain dendrite nucleation at solid electrolyte interfaces.[31]

Recent Outcomes: It will take time to see the long-term impact of BMWS. In the near-term, it has undoubtedly provided professional growth and enhanced visibility for early career researchers. There has been a significant upsurge in article reads/downloads for the works presented, with data accessed from IOP publishing[32] listed in Table 2. Refs. 10 and 11 had an increase in downloads from 70 and 152 to 1549 and 2060, respectively. Ref. 10 was recently featured in the Electrochemical Society April newsletter as one of the top downloaded articles.[33] Subsequent talks covering *J. Electrochem. Soc.* articles have also witnessed excellent growth in downloads, compared to at the time of seminar announcement; 156 to 501 for Feng *et al.*[28] and 633 to 1162 for Reniers *et al.*[29] In addition, one of the speakers (Verma) saw a 5000% rise in professional network views (LinkedIn) during the presentation week. Alongside this, the webinar series provides professional development to researchers new to the battery research area, as shown in the community messages in Fig. 5

Concurrent Developments: Beyond modeling, the wider battery and electrochemistry community has adopted virtual channels for knowledge dissemination. Energy storage webi-

nars have exploded in quantity, with 38 free-to-attend talks held in June 2020 alone.[34] While BMWS showcases early career researchers, Stanford's StorageX symposia have invited titans of the field, providing global access to plenary-level lectures once reserved for exclusive (and expensive) conferences.[35] The San Francisco Bay Area's monthly "Battery Brunch",[36] originally an informal gathering of local battery industry professionals, investors, policy makers, and academics, has more than doubled its membership (from 223 to 557) since updating

As a newcomer in the battery field, this webinar series shows me millions of things that battery modeling research can do. BMWS broadens my perspective on computational electrochemistry while also touches on bigger pictures in the battery world. It's the best way to prepare my upcoming graduate school while staying inside!
Jiankun Pu, Georgia Institute of Technology

I would like to thank the whole team - especially Dr.Viswanathan for creating this weekly webinar series during the pandemic which helped graduate students like me, who are in their early stages of career, to remotely gain exposure to the field of batteries. This opportunity gave me a bigger picture of battery research and helps me to choose my future path wisely.
**Shanthan Kumar P, The Ohio State University**

Figure 5: Community messages on professional development for early-career researchers.

to a virtual format in April 2020. Members of the BMWS community Andrew Wang and Nicholas Yiu have published an email newsletter called Intercalation Station.[37] The monthly newsletter covers battery technology developments in research and industry and highlights related lively dialogues from Twitter. YouTube is a growing platform for battery professionals, academics, and enthusiasts to share content, such as The Limiting Factor channel on battery patent reviews.[38] Webinar recordings have an added benefit of catering to asynchronous schedules. Undoubtedly, research communities across the energy storage domain are arriving at a new paradigm for sharing and discussing scientific progress.

Ref. 11	152	2060
Ref. 28	156	501
Ref. 29	633	1162

Sustainability and Inclusiveness: An important consideration is the carbon emissions mitigated by online conferencing. Battery researchers must be cognizant of the climate emergency, as international air travel dominates the carbon budgets of academics.[39] The BMWS community has welcomed ca. 650 unique attendees spanning 6 continents virtually, as shown in Fig. 2. To a first approximation, assuming attendees travel from their geographically-local major hub to a North American location, flights to and from an in-person BMWS conference would contribute approximately 700 tonnes of carbon dioxide equivalent (CO_2e).[40,41] Even applying a discount of 50% to account for lower in-person attendance, 350 tonnes CO_2e is comparable to the annual electricity consumption of 59 US households. Offsetting these emissions would require ca. 450 acres of US forest growth, annually. Putting into context of an individual researcher, flying from the UK to the US adds 1.2 tonnes to the 5.2 tonne carbon footprint of the average UK researcher.[42]
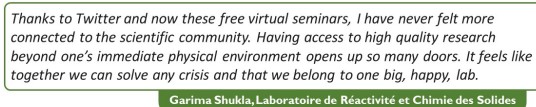

Conferences are places to cross-pollinate ideas and form friendships as well as collaborations. Although one forgoes the spontaneity and depth of face-to-face interactions, virtual

networking has other accessibility advantages. More-so than traditional settings, the flat hierarchy of virtual dialogue enables interaction between senior and junior researchers, and open dialogues lower the activation barrier for a more diverse set of BMWS members to contribute. Many of the exclusionary limitations such as funding, travel constraints, and caring responsibilities are also alleviated. Participants can choose to modulate their engagement based on availability. Most researchers have become adept with virtual social and collaborative tools in recent months. Going forward, this format serves as a valuable supplement to in-person meetings. However, this will require attendees to adapt to and stick with these new technologies for online engagement to be effective.

Outlook: Challenges and Opportunities A battery is a complex, developing system, and there are countless opportunities for a thriving and emerging online community. This includes but is not limited to expanded education for all participants, new collaborations, diverse engagement, generation of research ideas, and multi-disciplinary projects. There will be many challenges to adopt and grow a new medium, including finding a common dialogue and locus of expertise, overcoming language barriers, and maintaining high quality content. An important development area is bridging the collaboration gap between the largest industry players and the academic community in energy storage. Korea, China, and Japan host four of the top five manufacturers of lithium-ion batteries.[26] Inclusion of these groups will unlock great opportunities to deploy scientific advancements on larger scales.

An ambitious goal for this community is to perform global, massively collaborative, cutting-edge research in batteries, along the lines of the Polymath project.[43] There are numerous cross-disciplinary challenges in batteries and electric mobility.[44] Owing to the diverse backgrounds of our members, we could bring together a very unique approach to critical problems in battery science and technology. Additional open-source software and scientific tools[45,46] such as PyBaMM (Python Battery Mathematical Modelling) software,[47] MPET (Multiphase Porous Electrode Theory) software,[48] and Cantera,[49] will be needed to achieve this goal. Nonetheless, this article itself serves as an important proof point that distributed

self-assembled collaborations are possible. We view the entire community as one cohesive collaborative research enterprise, along the lines of the community message in Fig. 6

Thanks to Twitter and now these free virtual seminars, I have never felt more connected to the scientific community. Having access to high quality research beyond one's immediate physical environment opens up so many doors. It feels like together we can solve any crisis and that we belong to one big, happy, lab.

Garima Shukla, Laboratoire de Réactivité et Chimie des Solides

Figure 6: Community message on viewing the group as one big, happy lab!

As scientists, it is our duty to be at the forefront of positive innovation. We promote sustainable, positive behaviour change by interacting with one another, by suggesting an effective way to reduce environmentally deleterious networking. We see intense, emissions-heavy travel schedules as a thing of the past.[50] Furthermore, as scientists, we have to keep dreaming: maybe, one day, networking and conferences will happen with only minimal barriers, and become even more inclusive in virtual reality rooms.
